Nunc metus ipsum, euismod a consectetur vel, hendrerit nec nunc.

1.4 ChatGPT says

Thanks! I'll look into what it means for $\pi_1(E_2)$ to be a model for the Teichmüller tower, including how this connection is made precise in algebraic topology and geometry. I'll get back to you with a detailed explanation and any key references that clarify this relationship.

1.4.1 Little 2-Disks Operad and the Grothendieck-Teichmüller Tower

The Teichmüller tower is the profinite system formed by the fundamental groups of the moduli stacks $\mathcal{M}_{g,n}$ of algebraic curves (genus g , n marked points) and the natural maps between them (induced by forgetting or gluing marked points). By a theorem of Grothendieck, the geometric (étale) fundamental group of $\mathcal{M}_{g,n}$ is canonically the profinite completion of the mapping-class group $\Gamma_{g,n}$ of a genus- g surface with n punctures [2]. Thus the Teichmüller tower can be described purely in topological terms as the tower of all profinite completions $\widehat{\Gamma}_{g,n}$, together with

the natural homomorphisms induced by inclusions of subsurfaces [3]. In genus 0 this amounts to the tower of profinite mapping-class groups of spheres with marked points. One then defines the (profinite) Grothendieck-Teichmüller group $\widehat{\text{GT}}$ as the group of automorphisms of this tower commuting with the operadic/gluing maps [2]. For example, Ihara showed that the Galois action on $\pi_1(\mathcal{M}_{0,4}) \cong \widehat{F}_2$ lands in $\widehat{\text{GT}}$ [2], reflecting the faithful action of $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ on the whole Teichmüller tower.

The little 2-disks operad E_2 is the topological operad whose space of n -ary operations $E_2(n)$ is the space of configurations of n disjoint labeled embeddings of the unit disk into itself. Concretely, $E_2(n)$ is homotopy equivalent to the configuration space of n labeled points in \mathbb{R}^2 (or \mathbb{C}). A classical result (Arnol'd, Fadell-Neuwirth, etc.) is that each such configuration space is a $K(\pi, 1)$ with fundamental group the braid group on n strands. Equivalently, each $E_2(n)$ has no higher homotopy, so the topological operad E_2 is fully captured by its fundamental groupoid operad. In fact one can show:

1. Claim: The space $E_2(n)$ is a $K(\pi, 1)$ with $\pi_1(E_2(n)) \cong B_n$ (the braid group on n strands). In particular, there are no nontrivial higher homotopy groups. Thus the operad E_2 is (homotopy equivalent to) the operad in groupoids obtained by taking the fundamental groupoid of each $E_2(n)$ [4].

This means that, up to homotopy, E_2 is an operad whose n -ary part is essentially the braid group B_n , with operadic composition given by “inserting” braids into one another (the usual operadic substitution corresponds to concatenating configuration braids).

1.4.2 Moduli of genus 0 curves as an operad

The moduli spaces of genus-0 curves themselves carry an operadic structure. More precisely, let $\overline{\mathcal{M}}_{0,n+1}$ denote the Deligne-Mumford moduli of stable genus-0 curves with $n + 1$ marked points. Then the collection

$$\{\overline{\mathcal{M}}_{0,n+1}\}_{n \geq 1}$$

forms an operad in topological spaces (with no 0-ary part): the $n + 1$ points are viewed as n inputs and one output, and operadic composition is given by gluing the “output” of one curve to an input of another (creating a node) [2]. In more detail:

1. For each $n \geq 1$, $\overline{\mathcal{M}}_{0,n+1}$ is a (compact) complex manifold of dimension $n - 1$.
2. By a well-known result, for $n \geq 3$ it is isomorphic (analytically) to the configuration space of $n + 1$ distinct points on \mathbb{CP}^1 modulo $\text{PGL}_2(\mathbb{C})$.

2. The operad structure is given as follows: if we have one stable curve with $n + 1$ markings and another with $m + 1$ markings, we glue the marked output of one to the k -th input of the other. The resulting nodal curve lies in $\overline{\mathcal{M}}_{0,n+m}$ [2]. Composition is associative and Σ_n -equivariant in the obvious way.

Thus $\overline{\mathcal{M}}_{0,\bullet+1}$ is a modular operad (or in fact a cyclic operad) encoding the combinatorics of stable genus-0 curves. At the level of fundamental groups, this operad structure corresponds to the usual inclusions and gluing of mapping-class groups of spheres with punctures.

A key connection to the little disks operad was established by Drummond-Cole: there is a homotopy pushout diagram of operads relating the framed little 2-disks operad FD to the moduli operad $\overline{\mathcal{M}}_{0,\bullet+1}$ [2]. Concretely, $FD(n)$ differs from the non-framed $E_2(n)$ by allowing each little disk to rotate (so $FD(n) \simeq E_2(n) \times (S^1)^n$). Drummond-Cole showed that “killing” the S^1 -rotation in arity 1 in FD yields an operadic quotient equivalent to the moduli operad [2]. In other words, the genus-0 surface operad M (classifying spaces of spheres with boundary circles) maps onto $\overline{\mathcal{M}}_{0,n+1}$ by collapsing the boundary circles; by a theorem of Drummond-Cole, this map is an operadic homotopy quotient obtained by contracting the circle in arity 1 [2]. Equivalently, one can say the genus-0 surface operad M (or FD) and the moduli operad $\overline{\mathcal{M}}_{0,\bullet+1}$ become equivalent once one trivializes the S^1 -factor.

Because of this equivalence, the fundamental group operad of E_2 (or of framed E_2) “models” the tower of mapping class groups for genus 0. Indeed, as noted above, $E_2(n)$ has π_1 the n -strand braid group B_n . Topologically, a sphere with $n + 1$ boundary components has a mapping class group which fits in a split extension

$$1 \rightarrow \mathbb{Z}^n \rightarrow \Gamma_{0,n}(\text{with boundary}) \rightarrow \Gamma_{0,n}(\text{punctured sphere}) \rightarrow 1,$$

where the \mathbb{Z}^n comes from rotating each boundary circle [3]. Collapsing the boundaries recovers the pure mapping-class group of the sphere with n punctures. But as operads these spheres-with-boundaries $\Gamma_{0,n}$ assemble exactly into an operad homotopy equivalent to the little disks operad [3][2]. Put succinctly:

1. The mapping-class groups of genus-0 surfaces with boundaries form a modular operad under gluing of boundary components [3]. Its genus-0 part (spheres with $n + 1$ boundary components) is often called the genus-0 surface operad.
2. This surface operad M is homotopy equivalent to the (framed) little disks operad FD (and hence to E_2 up to the extra S^1 -factors) [2].

Since each $E_2(n) \simeq FD(n)$ is $K(\pi, 1)$ with $\pi = B_n$, it follows that taking fundamental groupoids recovers the pure braid operad (or more precisely the operad of pure braids, which is also the operad of classifying spaces of these mapping-class groups). In this sense $\pi_1(E_2)$ is exactly an operadic model for the genus-0 Teichmüller tower: its n th piece is the (profinite) mapping class group of a sphere with $n + 1$ points (or boundaries). Hatcher-Lochak-Schneps originally described an “operadic” version of the Teichmüller tower by using boundary-based mapping-class groups, and one recovers the same structure from E_2 [3] [2].

1.4.3 Profinite completion and the Grothendieck-Teichmüller group

Because each $E_2(n)$ (and each moduli space $\overline{\mathcal{M}}_{0,n+1}$) is defined over \mathbb{Q} , one can consider its profinite completion. The result is that $\widehat{E_2}$ (the collection of profinite homotopy types of $E_2(n)$) is an operad in profinite spaces whose fundamental progroups are the profinite braid groups \widehat{B}_n (equivalently, the profinite mapping class groups $\widehat{\Gamma}_{0,n+1}$). A remarkable result of Boavida de Brito-Horel-Robertson is that the profinite automorphism group of this entire profinite operad is isomorphic to the profinite Grothendieck-Teichmüller group [2]. Equivalently, any automorphism of the little-disks operad up to homotopy (in the profinite or completed sense) comes from an element of $\widehat{\mathbf{GT}}$. In their words: “the group $\widehat{\mathbf{GT}}$ is isomorphic to the group of homotopy automorphisms of the profinite completion of the genus zero surface operad” [2]. This shows that $\pi_1(E_2)$ (profinite fundamental groupoid of E_2) indeed encodes the full genus-0 Teichmüller tower and its $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -action. In particular, $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts faithfully on the profinite π_1 of E_2 (equivalently on the profinite braids operad) via its embedding into $\widehat{\mathbf{GT}}$ [2].

Summarizing, the little 2-disks operad E_2 (or its framed version) provides a topological model for the genus-0 part of the Teichmüller tower. Its operadic structure mirrors the gluing of genus-0 curves, its homotopy groups are the braid/mapping-class groups, and its profinite completion carries the $\widehat{\mathbf{GT}}$ -action. For further details see, e.g., Boavida de Brito-Horel-Robertson, [2], and Hatcher-Lochak-Schneps (2000) or survey articles on Grothendieck-Teichmüller theory.

Key references: The operadic realization of the Teichmüller tower is explained in Hatcher-Lochak-Schneps, “On the Teichmüller tower of mapping class groups,” *J. Reine Angew. Math.* 521 (2000), and in lecture notes by Borghi-Robertson [3]. The work of Boavida de Brito-Horel-Robertson (2020) establishes rigorously that $\widehat{\mathbf{GT}}$ equals the automorphism group of the profinite little-disks operad [2]. Finally, the fact that $E_2(n)$ is $K(\pi, 1)$ with π a braid group is classical [4]. These and other

sources give a thorough account of how $\pi_1(E_2)$ encodes the genus-zero Grothendieck-Teichmüller structures.
